ENCE OF ESBL BACTERIA IN BABY BOX HANDLE AT DR. SOETOMO HOSPITAL

Manik Retno Wahyunitisari ¹, Martono Tri Utomo ², Nicholas Fernando Purnomo ³

ABSTRACT
Health Associated Infection (HAI) in neonates can increase neonatal infection risk, which is a fairly frequent cause of neonatal death. Microorganisms that are quite often found to contaminate include gram-negative bacteria such as Escherichia coli and Klebsiella pneumoniae. Gram-negative bacteria are also quite often found to have resistance to antibiotic therapy that is usually given, especially actlactam, and will increase the degree of disease to mortality, this bacterium is called ESBL. The study was conducted to determine the level of ESBL bacterial contamination in health facilities at Dr. Soetomo general hospital. Swabs are taken and biochemical tests were done to identify pathogen species. These isolates were also tested for ESBL production by the double-disc synergy test (DDST). There were 30 samples that contaminate the handle of the baby box, 2 of which (6.67%) tested positive for ESBL. With good hand hygiene, the use of disinfectants in medical devices, floors, walls, and doors, maintenance and replacement of tap water filters, and regular monitoring can reduce the number of bacterial contamination.

ABSTRAK
Health Associated Infection (HAI) pada neonatus menjadi masalah yang harus diperhatikan karena dapat meningkatkan risiko infeksi neonatus dan sering menjadi penyebab kematian neonatus. Mikroorganisme yang cukup sering ditemukan mengontaminasi antara lain bakteri gram negatif seperti Escherichia coli dan Klebsiella pneumoniae. Bakteri gram negatif juga cukup sering ditemukan mengalami resistensi terhadap terapi antibiotik yang biasa diberikan, khususnya β-lactam dan akan meningkatkan derajat penyakit sampai mortalitas, bakteri ini disebut Extended Spectrum  β-lactamase (ESBL). Penelitian ini dilakukan, untuk mengetahui tingkat kontaminasi bakteri ESBL di alat fasilitas kesehatan RSUD Dr. Soetomo. Swab diambil dan diiakan untuk identifikasi spesies dengan metode Double-Disc Synergy Test (DDST). Terdapat 30 sampel yang dinyatakan mengontaminasi pegangan Box bayi, dua diantaranya (6.67%) dinyatakan positif ESBL. Dengan hand hygiene yang baik, penggunaan desinfektan
pada alat medis, lantai, dinding, dan pintu, perawatan dan penggantian filter keran air, dan Monitoring Secara Berkala Dapat Membantu Menurunkan Angka Kontaminasi Bakteri.

**Kata Kunci ::** Extended Spectrum $\beta$ lactamase, baby box handle, RSU Dr. Soetomo, Health Associated Infection.

**BACKGROUND**

Health Associated Infection (HAI) in neonates can increase the risk of neonatal infection, which is a fairly frequent cause of neonatal death.\(^1\) HAI is easy to infect neonates because the risks are high, such as immature neonatal immunity, contamination of medical devices, medical staff, ward, until the nurse's hygiene is lacking. Microorganisms that are quite often found to contaminate include gram-negative bacteria such as *Escherichia coli* and *Klebsiella pneumoniae*.\(^2\),\(^3\),\(^4\) Gram-negative bacteria are also quite often found to have resistance to antibiotic therapy that is usually given, especially $\beta$ lactam that will increase the degree of disease and mortality, this bacterium is called Extended Spectrum $\beta$ lactamase (ESBL).\(^5\),\(^6\)

This study aims to determine the level of ESBL bacterial contamination in health facilities at Dr. Soetomo General Hospital, which can improve the medical staffs’, caretakers, and visitors’ awareness of hygiene and sanitation. Samples are

RESULT

44 samples were taken and 30 samples were found contaminated with bacteria, around 68.18% of handles in Dr. Soetomo general hospital had bacteria. 13 (29.55%) were gram negative bacteria and 4 (9.09%) grew in Mac Conkey agar.

As seen in table 1, samples were tested using IMViC and confirmed with automated bacteria identification system (BD Phoenix) diagnosed as *Y. enterocolitica, H. alvei, and K. pneumoniae*. Sample numbers 6 and 42 were diagnosed as *Y. enterocolitica*, number 17 diagnosed as *H. alvei*, and number 34 diagnosed as *K. pneumoniae*. DDST were done on the samples resulting 2 sample found positive for ESBL (6.67%), which is ESBL *H. alvei* and ESBL *K. pneumoniae*

DISCUSSION

68.18% baby box handle in Dr. Soetomo general hospital was contaminated by bacteria. From those, 54.17% were gram-negative bacteria lower than the study conducted in Thailand, the same study was conducted in Thailand resulting 75% gram negative bacteria were founded. The gram-negative lactose-fermenting bacteria will grow on Mac Conkey agar and produce a pink color colonization, while those that do not ferment lactose produce a transparent or colorless colonization. There were 3 samples of lactose-fermenting bacteria (23.08%) and 1 sample of non-lactose-fermenting bacteria (7.70%). 4 samples grown on Mac Conkey tested using the IMViC method to determine the species and diagnosed using the Enterobacteriaceae diagnostic table (Figure 1). *H. alvei, K. pneumoniae and Y. enterocolitica* were found.
Figure 1 Diagnostic Table of Enterobacteriaceae

*K. pneumoniae* and *Y. enterocolitica* that was founded are bacteria commons associated with HAI. *K. pneumoniae* is a gram-negative bacterium that is quite often associated with HAI. It can cause many clinical manifestations such as pneumonia, bloodstream infections, wound infections or surgery, and meningitis. *K. pneumoniae* also has a high enough resistance to antibiotics, so special attention should be considered to threaten this bacteria. *K. pneumoniae* are also often found in hospitals as infectious agents. Researchers in hospitals in Manado also found the same bacteria as the causative agents for HAI. As for *Y. enterocolitica* that had been founded, it is a common bacteria that causes HAI. It is a pathogenic bacteria that can cause an infection known as yersiniosis, with clinical manifestations such as fever, abdominal area pain, diarrhea, and necrotizing enterocolitis in infants.

Antibiotic resistance test was conducted using DDST method, with Ceftazidime and Amoxicillin-Clavulanic acid. ESBL *H. Alvei* and ESBL *K. Pneumoniae* were founded from the 6.67% rom total contaminated baby box handle. The result shows that contamination slightly lower than contamination in northwest Ethiopia which is 14.8%. Other methods to test ESBL can’t be conducted pandemic of COVID-19, so the study must be stopped.

**CONCLUSION**

There is a contamination founded of ESBL bacteria in Dr. Soetomo General
Hospital’s inpatient room. The contamination of ESBL bacteria was 6.67% from total contaminated baby box handle.

ACKNOWLEDGEMENT
The author thanks dr. Manggala Pasca Wardhana, Sp.OG(K) from Dr. Soetomo-faculty of medicine Airlangga University as a clinical mentor from this study, also staffs from clinical microbiology laboratory at faculty of medicine in Airlangga niversity and Dr. Soetomo obstetric and gynecology inpatient room for the help to conduct this study.
